

Focus on conservatories

Your conservatory should become an oasis of relaxation. But people and nature have put sweating before relaxation.

When planning and executing your conservatory, numerous requirements and regulations from building law must be observed. For this reason alone, both belong in the hands of experts. Four things are particularly important for planning and implementation: the right glass and frame construction, adequate ventilation, and shading.

Thermal insulation glass helps you save energy when it is cold outside. With the help of solar radiation, they extend the period in which the conservatory is "habitable". However, they do not let out any heat even in summer. This must be taken into account when planning ventilation and shading.

Solar protection glass is an excellent design element. It delays the heating of your conservatory in summer but cannot completely replace shading. Therefore, do not go without shading or the option of corresponding retrofitting.

Moisture occurs in every conservatory. This is ensured, among other things, by the attractive plants there. The correct use is a central task for the details of the construction and the design of the ventilation. Especially here it is therefore important to deal correctly with the laws of nature.

Only specialist knowledge can help ensure that everything is really considered when planning your conservatory. The execution also must meet the highest demands and should therefore be a task for people from the specialist field.
